# Motivation

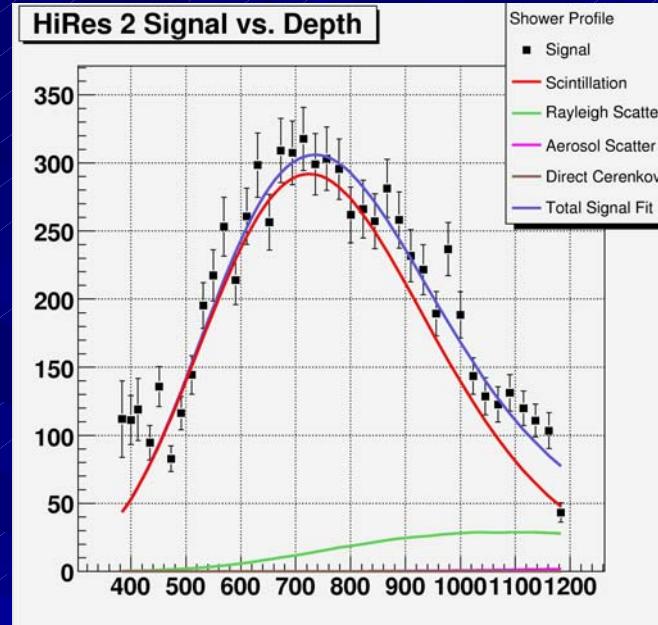

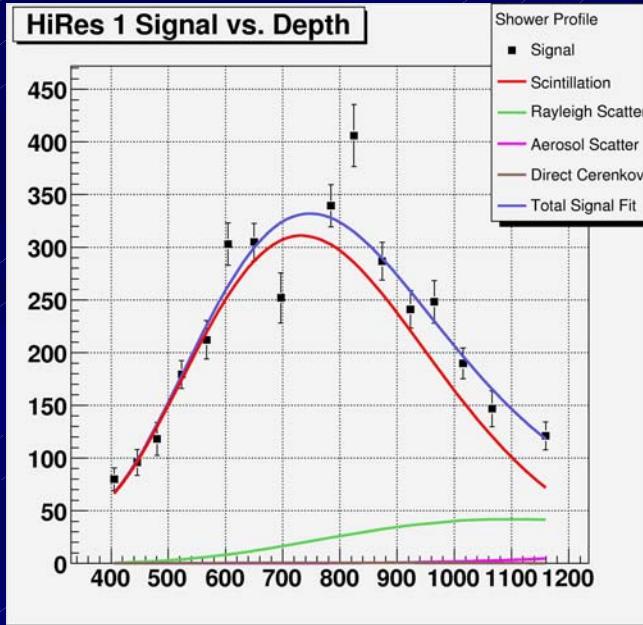

- Learn basic information about cosmic rays;
- In HiRes energy range ( $10^{17.2}$ - $10^{20}$  eV) expect to see a transition between galactic and extragalactic sources:
  - Expect highest energy galactic cosmic rays to be heavy nuclei (iron);
  - Expect extragalactic cosmic rays to be light (protons)
- Fluorescence experiments observe  $X_{\max}$  directly:
  - $\langle X_{\max} \rangle$  for proton >  $\langle X_{\max} \rangle$  for iron;
  - Can see the difference directly.
- Cosmic ray physics.
  - Proton-air inelastic cross-section significantly influences the development of cosmic ray showers.
- High energy physics.
  - Proton-air inelastic cross-section can be used to determine p-p total cross-section energy dependence.
  - Is the Froissart bound saturated?
- Strong model dependence of the previous cosmic ray measurements.

# Air shower profile.

- $X_{\max}$  ( $\text{g/cm}^2$ ) – slant depth of the shower where ionization losses start to exceed bremsstrahlung;
- $X_{\max}$  fluctuates event by event, but  $\langle X_{\max} \rangle$  is a stable function of energy;
- $\langle X_{\max} \rangle$  different for light and heavy component;
- RMS of the  $X_{\max}$  distribution is different for different primary.
- $X_1$  – depth of the first interaction.
- $X' = X_{\max} - X_1$ .

# Measured shower profile.

## Measured shower parameters.

### Event by event:

- $X_{\max}$  in g/cm<sup>2</sup>; →
- Total energy of the primary particle;
- Arrival direction

### Statistically:

- $p$ -air inelastic cross-section;
- Mass composition.

# Atmosphere

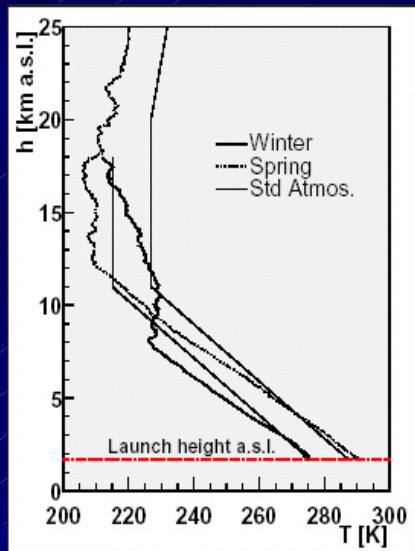

- Composition and cross-section measurements rely on knowledge of our calorimeter – the earth atmosphere;
- Choosing a correct atmospheric model will reduce the experiment's systematic errors;
- Atmospheric fluctuations will contribute to the statistical error.

# HiRes Atmospheric model

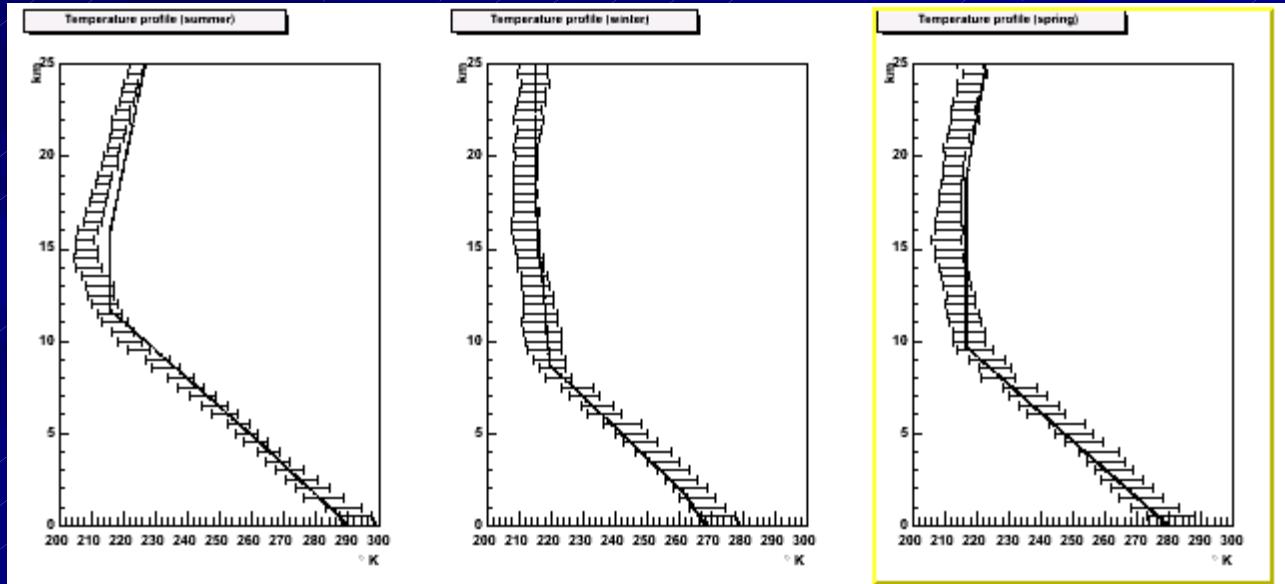

- 1976 US Standard Atmosphere
- 3 seasonal profiles: winter, summer, spring/fall
- For reconstruction the model is picked according to the season.
- Dec, Jan, Feb – winter
- June, July, Aug – summer
- All other months – spring/fall.

Using HiRes model.

Xmax2 – radiosonde  
Xmax0 – HiRes model

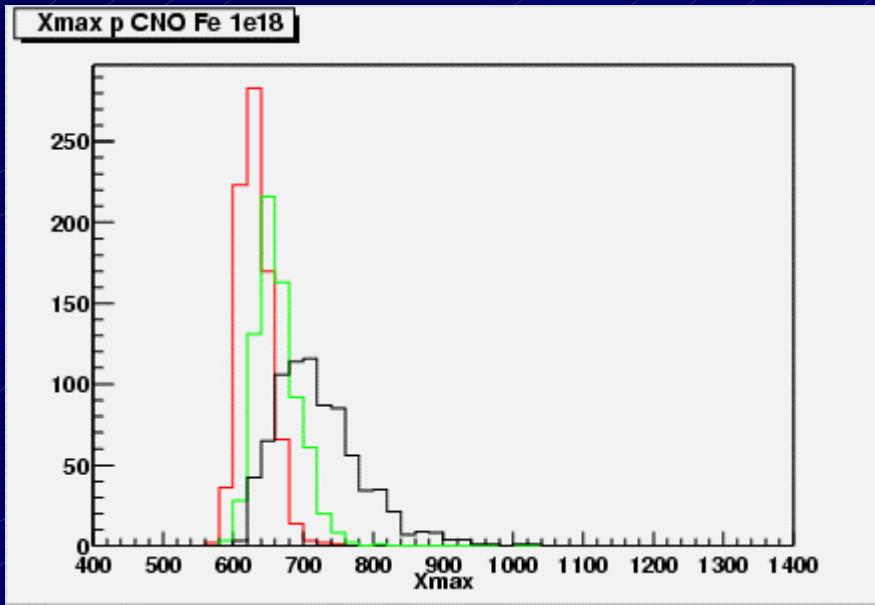

HiRes underestimates  $X_{\max}$   
By 13 g/cm<sup>2</sup>.

Effect on the elongation rate  $\sim 0.6$  g/cm<sup>2</sup>

# Molecular atmosphere. Conclusions...

- HiRes molecular atmosphere is very stable;
- HiRes atmospheric model uncertainty leads to  $\sim 10\text{-}13$  g/cm<sup>2</sup> energy-independent underestimation of  $\langle X_{\max} \rangle$ .

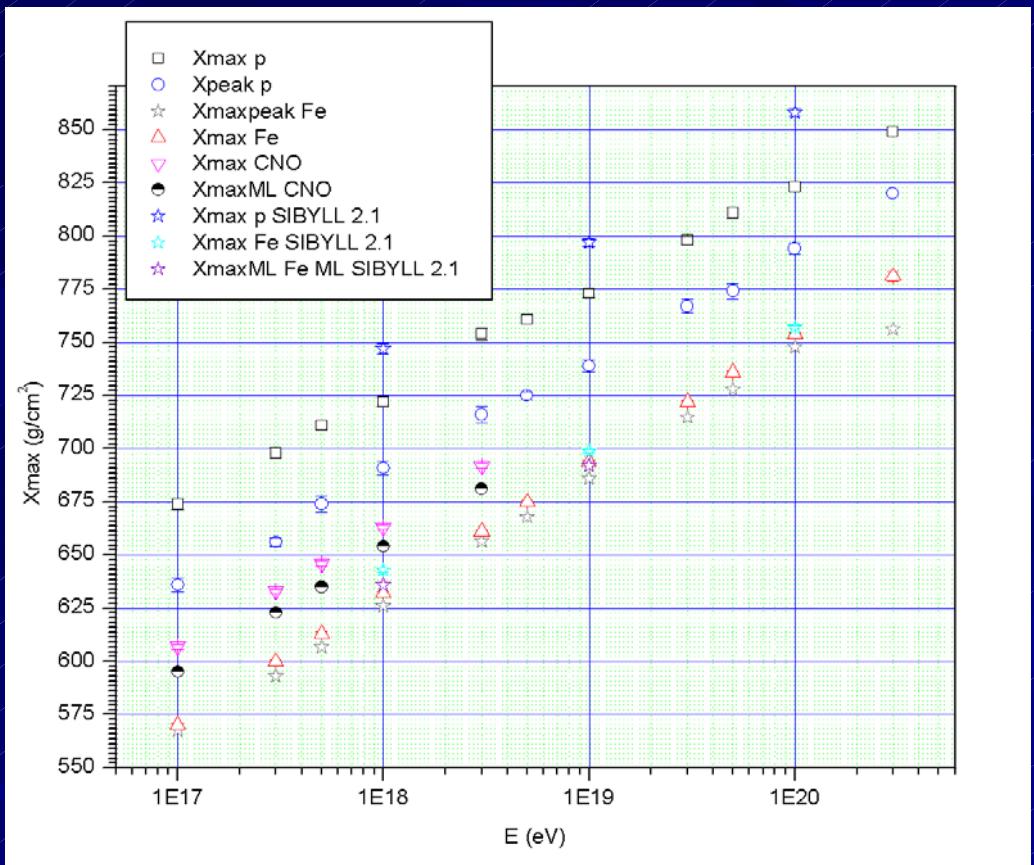

# $X_{\max}$ distribution for p, CNO, Fe

- Heavier primaries develop earlier in the atmosphere.
- RMS of the  $X_{\max}$  distribution is different.

QGSJet

# Elongation rate p, CNO, Fe

$\langle X_{\text{max}} \rangle$  can give us a clue about CR composition, but is very much model dependant.

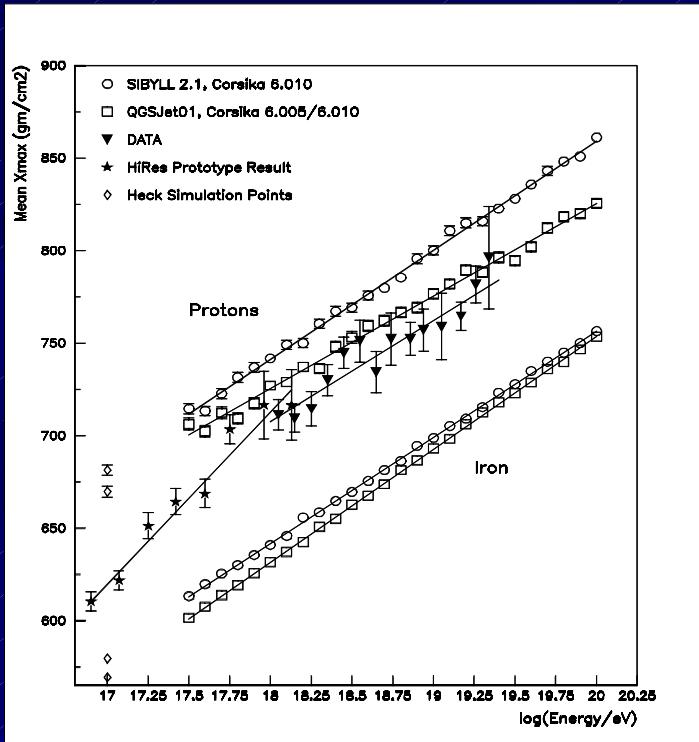

# Fly's Eye detector.

- Two fluorescence detectors were positioned 3.5 km apart;
- The effective energy range extended from  $10^{17}$  eV to  $3 \times 10^{19}$  eV;
- 5×5 degree pixel size;
- Geometry of the event was determined by the intersection of the two event-detector planes;
- Elevation angle range from 0 to 90 degrees;
- FE II had only partial azimuth coverage

# HiRes prototype/MIA

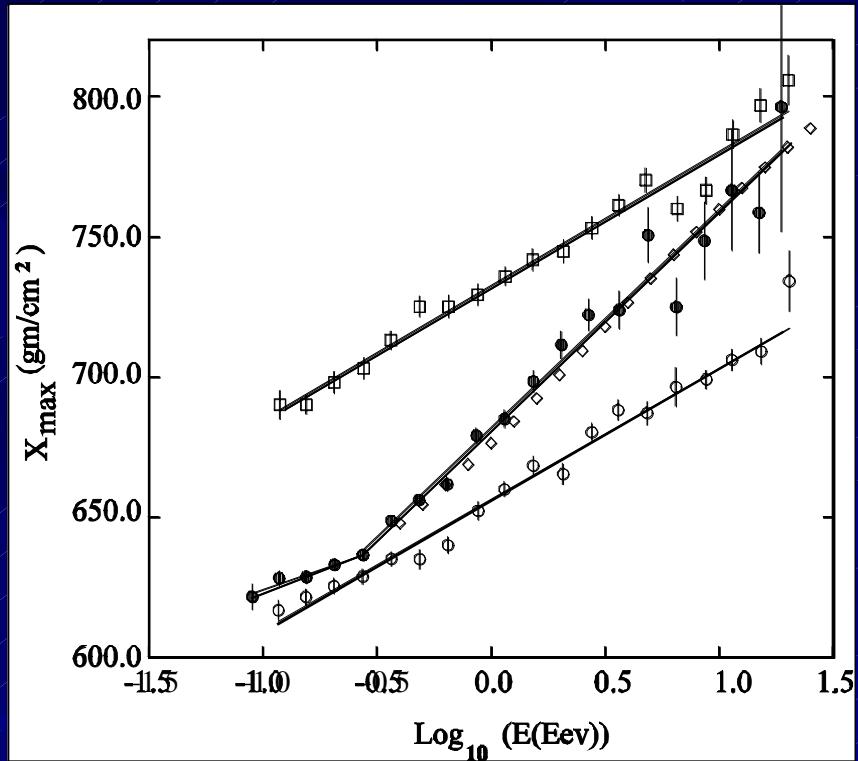

- Hybrid fluorescence - muon array detector;
- Fourteen mirror prototype of the current HiRes detector had a  $1 \times 1$  degree pixel size;
- Was located 3.5 km from the center of the MIA muon array;
- The muon array sampled a part of muon lateral distribution. 3 km effective area;
- Energy range from  $5 \times 10^{16}$  eV to just above  $10^{18}$  eV;
- Event geometry was determined by using the HiRes event-detector plane and timing from both detectors.

# HiRes stereo and HiRes prorotype data.

- HiRes/MIA - hybrid experiment. Resolution function estimated from simulations  $\sim 45 \text{ gm/cm}^2$
- HiRes stereo -  $X_{\text{max}}$  resolution measured,  $30 \text{ gm/cm}^2$

# Fly's Eye stereo data.

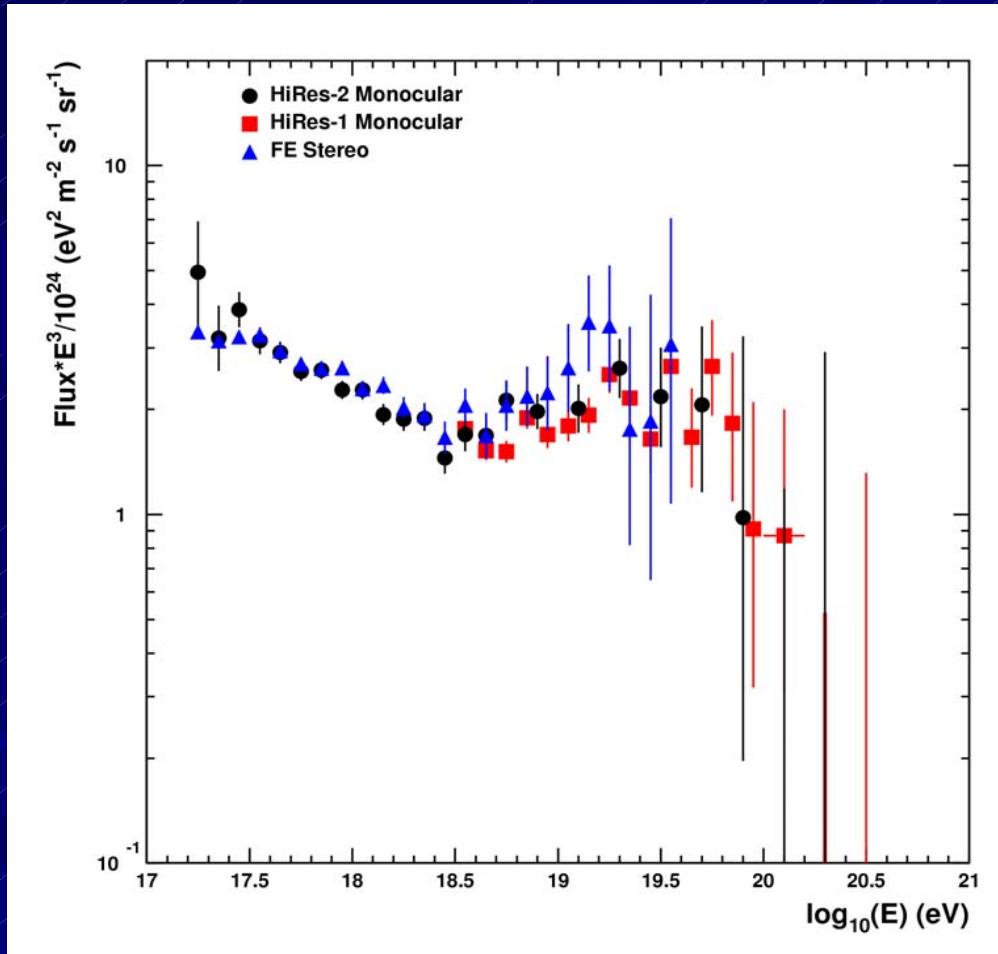

- Fly's Eye Stereo -  $X_{\max}$  resolution  $\sim 45$  gm/cm<sup>2</sup> measured resolution function

# Systematic errors

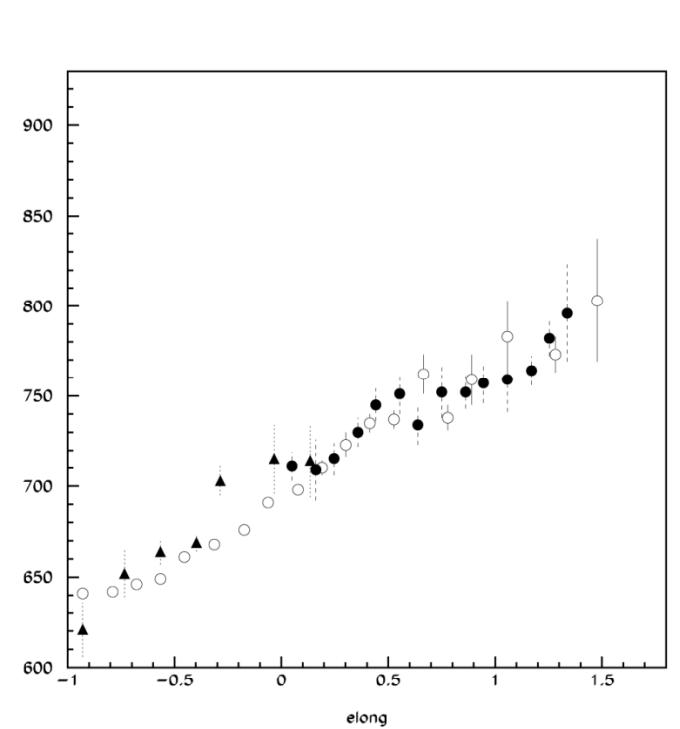

- All three experiments quote systematic errors  $\sim 25$  gm/cm<sup>2</sup>.
- Dominant contributions
  - Mirror survey
  - Cherenkov subtraction
  - Atmospheric profile
  - Aerosol corrections
- Highest energy data is best measurements
  - most complete profile
  - minimum Cherenkov subtraction

# Comparison of Fly's Eye Stereo and HiRes energy scales

Energy scale for all three experiments is consistent (location of ankle and second knee).

# Elongation rate

Filled circles, HiRes; Triangles,  
HiRes/MIA, Open circles, Fly's Eye  
(shifted).

Use HiRes stereo average  $X_{\max}$   
and Fly's Eye stereo average  
 $X_{\max}$  above  $10^{18}$  eV.

Require a  $13 \text{ gm/cm}^2$  upward shift  
for Fly's Eye to bring means  
into agreement

Shift all Fly's eye  $X_{\max}$  data points  
by the same amount.

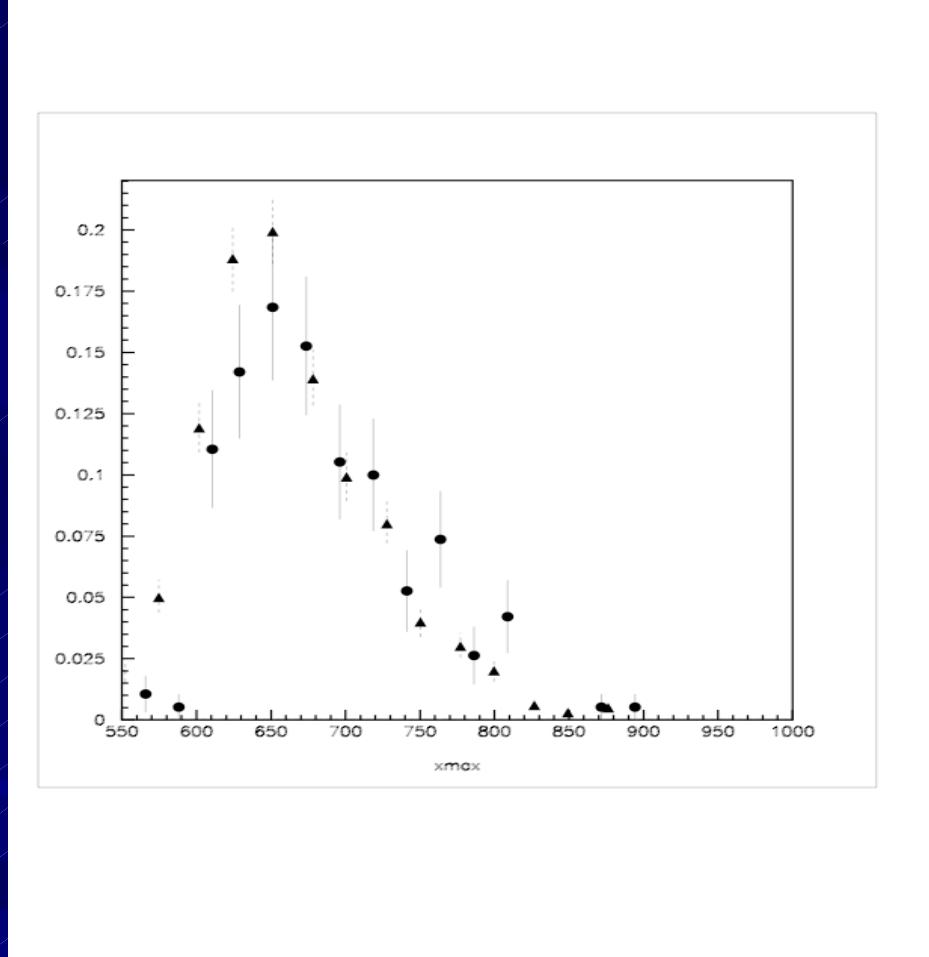

# Elongation Rate

- Simple shift of Fly's Eye data brings all data into reasonable agreement.
- Fly's Eye and HiRes data are in excellent agreement above  $10^{18}$  eV.
- HiRes/MIA shows earlier transition to “protons”, but point by point discrepancy is small.
- HiRes/MIA systematics are better understood, however.

# $X_{\max}$ distributions consistent?

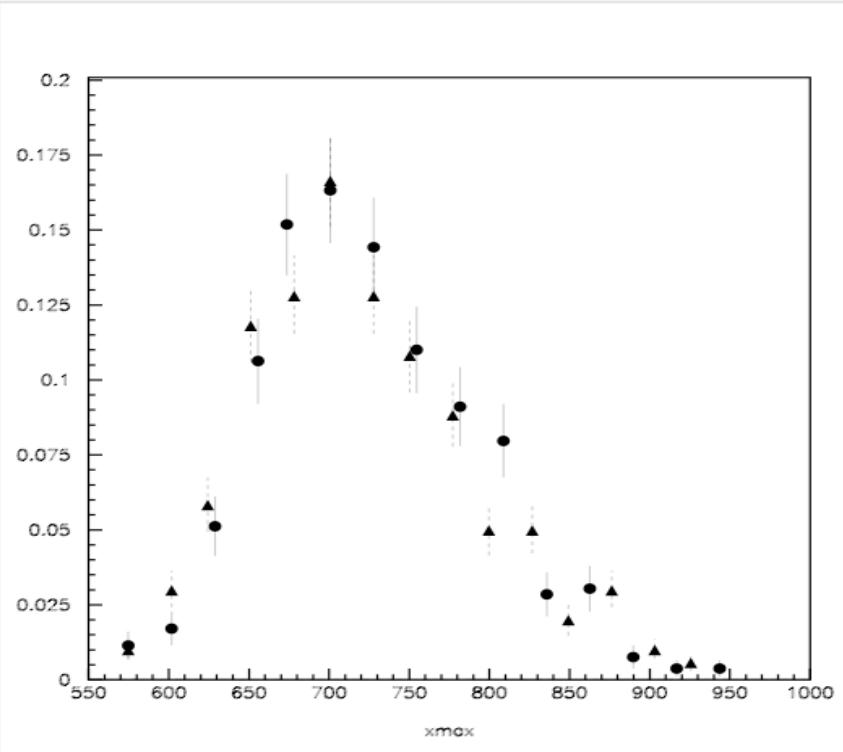

- Are  $X_{\max}$  distribution widths consistent?
- Two overlap regions
  - Fly's Eye and Hires/MIA in  $3 \times 10^{17}$  to  $5 \times 10^{17}$  eV bin.
  - Fly's Eye and HiRes stereo in  $> 10^{18}$  eV bin.
- No evidence of discrepancy in distribution widths.

# Fly's Eye vs HiRes/MIA $X_{\text{max}}$ at $3-5 \times 10^{17}$ eV

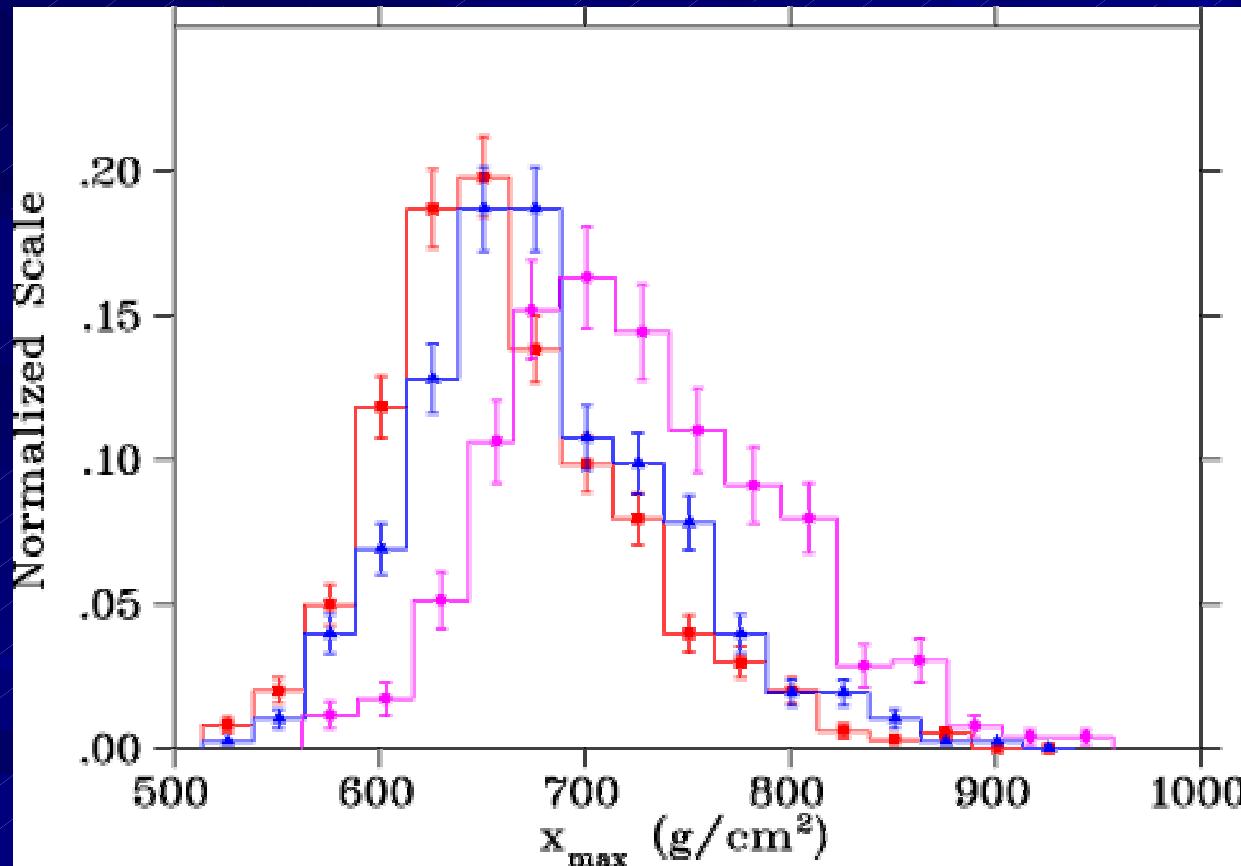

Triangles: Fly's Eye Stereo;  
Circles: HiRes/MIA.

# Fly's Eye vs HiRes $X_{\max} > 10^{18}$ eV

Triangles: Stereo Fly's Eye;  
Circles: HiRes.

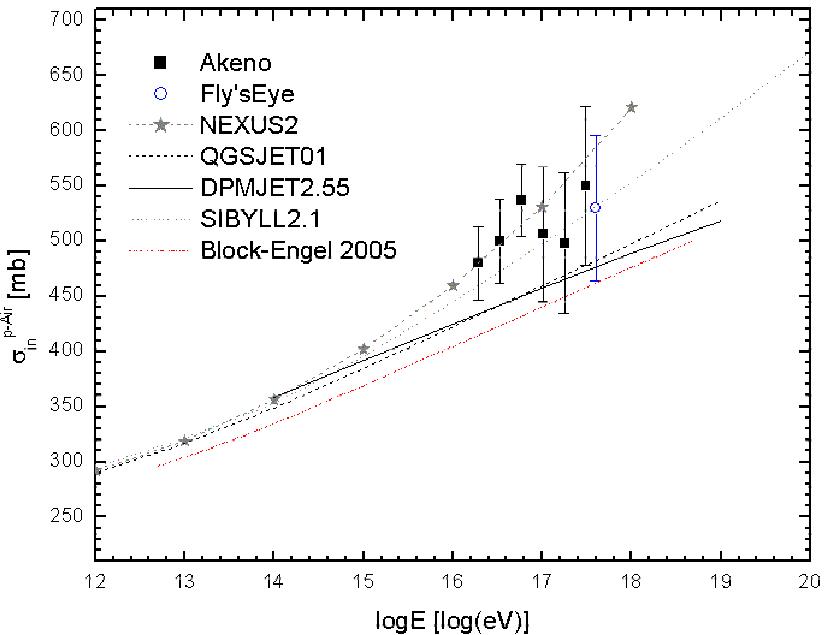

# Sequence of $X_{\max}$ distributions in three increasing energy bins $3-5 \times 10^{17}$ , $5-10 \times 10^{17}$ and $> 10^{18}$ eV.

# Mass composition. Conclusions...

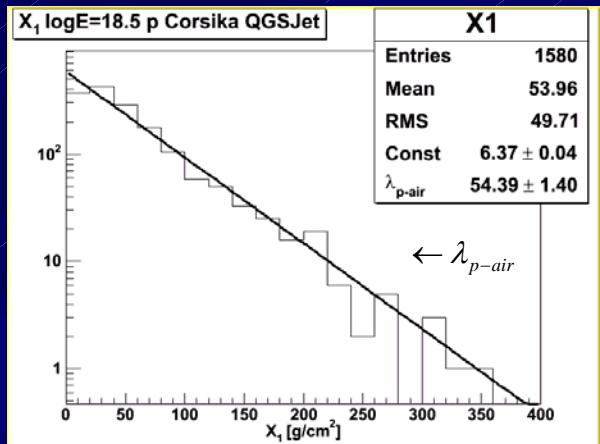

- A simple  $X_{\max}$  shift brings all three experiments into reasonable agreement.
- Widths of  $X_{\max}$  distributions are in agreement.
- Normalized  $X_{\max}$  distribution show jump to wider distribution above  $10^{18}$ , consistent with change to protons.
- Interpretation of elongation rate over limited energy range is problematic - Need large dynamic range in a single experiment!

# Cross-section: models and accelerator data extrapolation

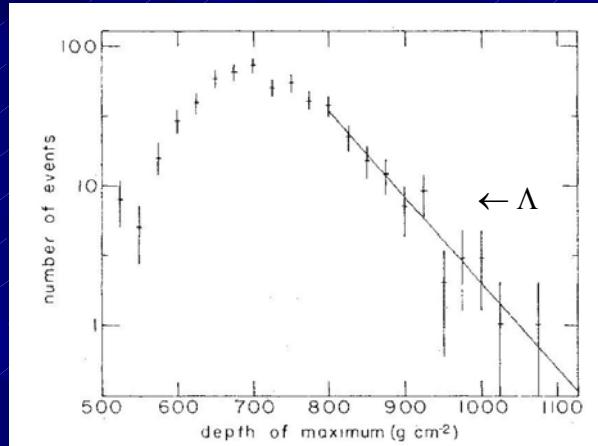

- Model uncertainties are large;
- Extrapolation goes orders of magnitude;
- AGASA and Fly's Eye measurements are model dependant.

# CS measured by Fly's Eye and AGASA

$$k\lambda_{p\text{-air}} = \Lambda$$

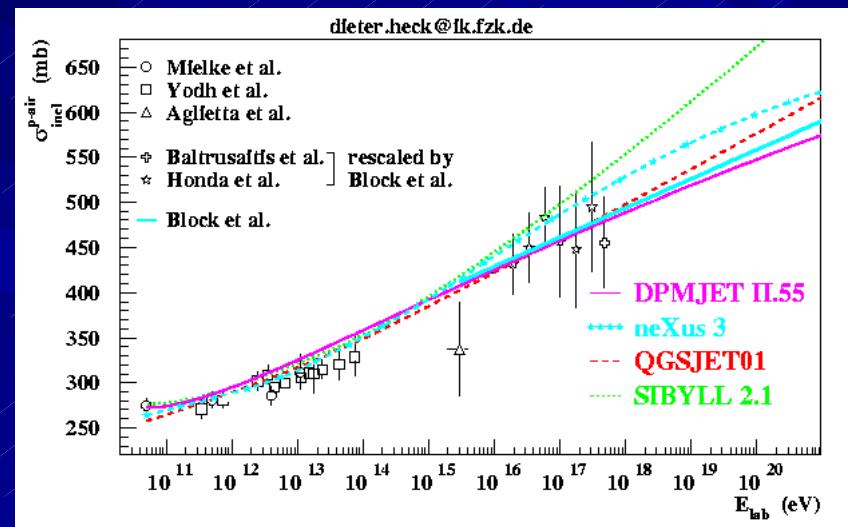

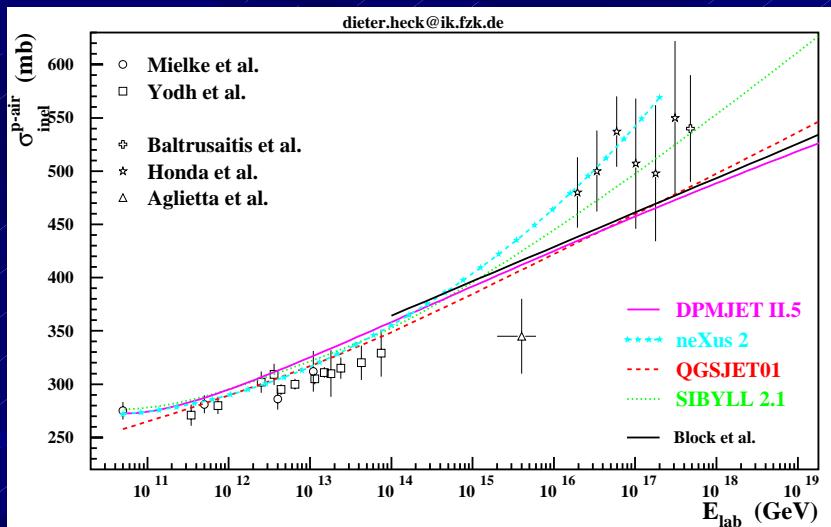

Baltrusaitis *et.al.* 1984.

$k$  – is obtained from MC study.

- An indirect measurement technique proposed for Fly's Eye and Akeno.
- The distribution of the point of first interaction (X1 distribution) propagates into the Xmax distribution and manifests itself in its exponential tail.

# $k$ -factor limitations.

- $k$  is dependent on the interaction model;
- $\Lambda$  measurement depends on the  $X_{\max}$  exp. slope cutoff point.

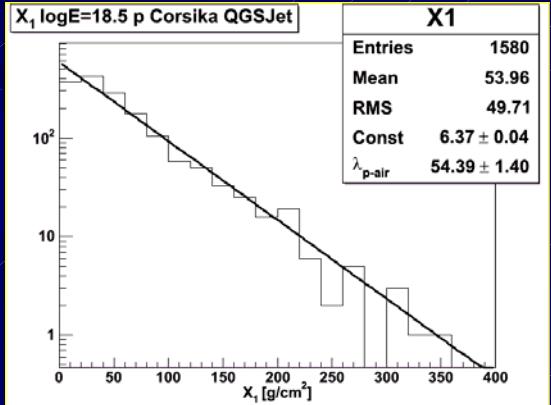

# HiRes stereo observables.

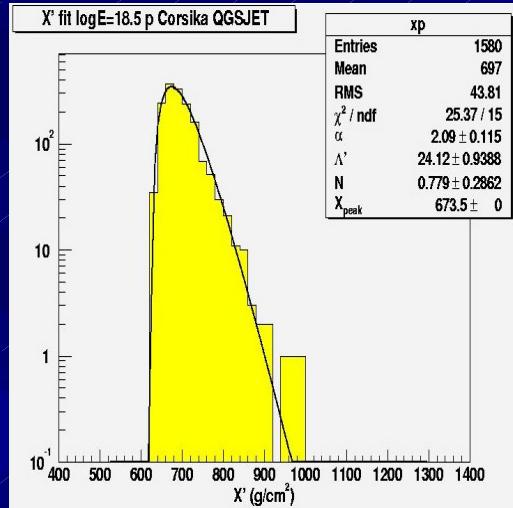

- Being an air fluorescence experiment HiRes stereo observes  $X_{\max}$  directly;
- Calorimetric measurements of the primary particle energy;
- Can still use  $X_{\max}$  distribution to measure the p-air inelastic cross-section, but a new technique is needed to reduce the interaction model dependence.

# Deconvolution technique. MC simulations.

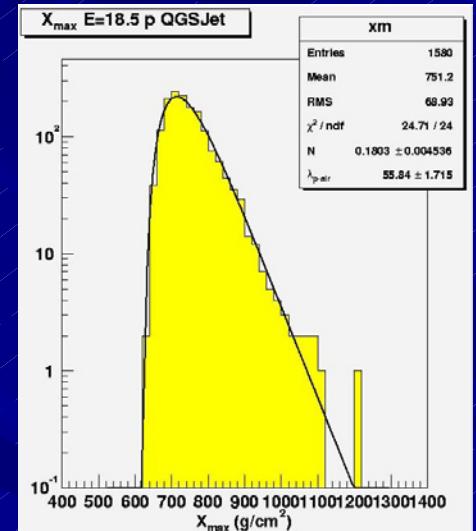

Point of first interaction distribution. Exponential index reflects inelastic Cross-section

Atmospheric part of air shower fluctuations

X<sub>max</sub> distribution

$$f_{\text{int}} = e^{-\frac{x_1}{\lambda_{p\text{-Air}}}};$$

$$\lambda_{p\text{-Air}} = \frac{1}{\tilde{n} \sigma_{p\text{-air}}^{inel}};$$

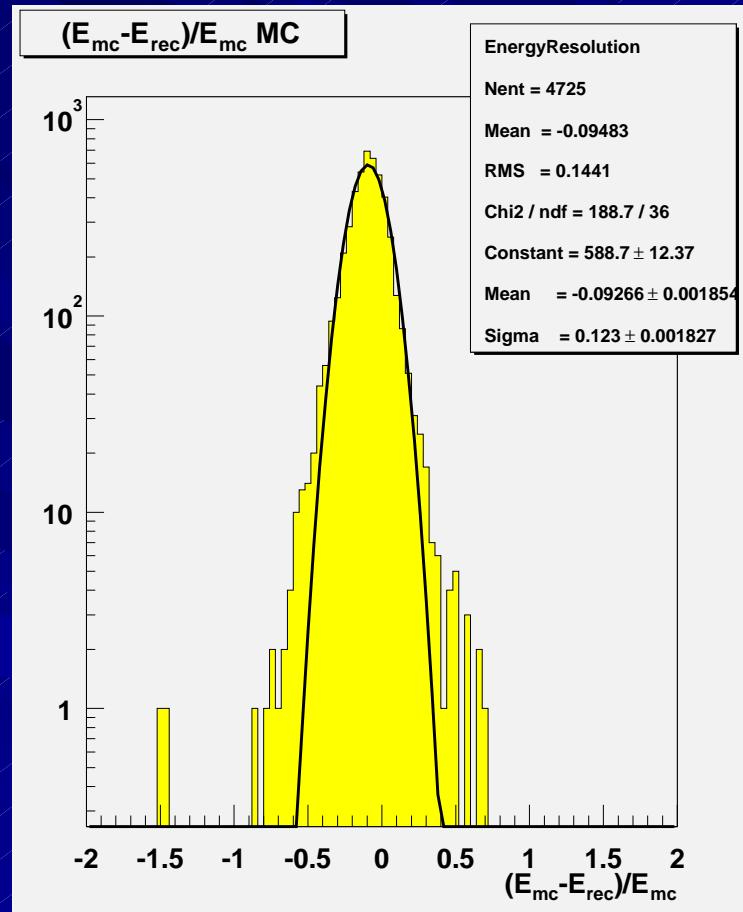

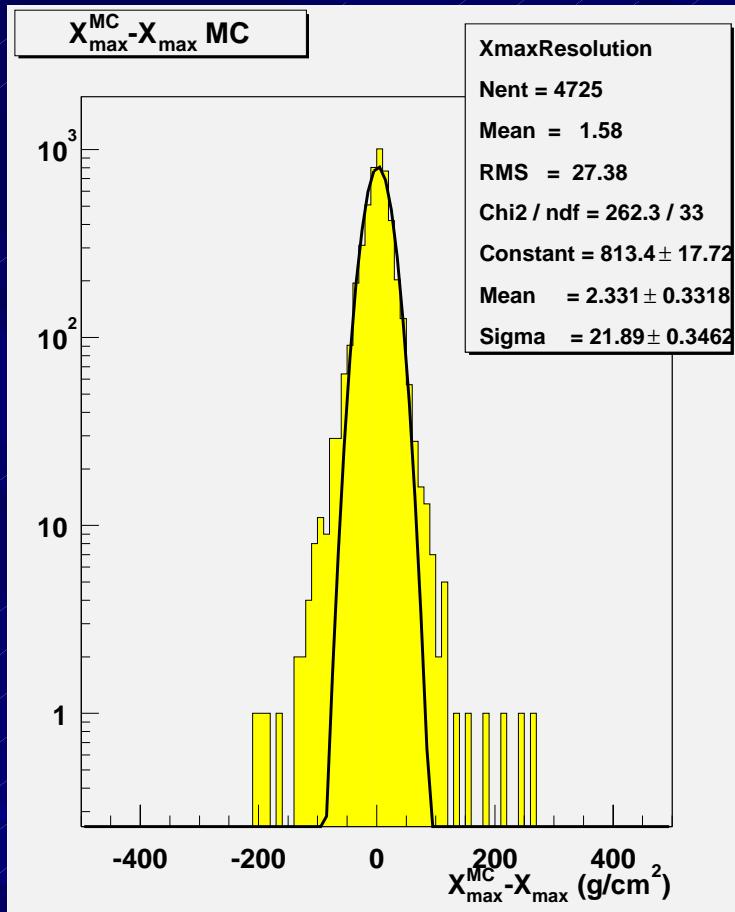

$$X' = X_{\text{max}} - X_1$$

$$f_{\text{fluct}} = \left[ \frac{x_{\text{max}} - x_{\text{peak}} - x_1 + \Lambda' \alpha}{e} \right]^{\alpha} e^{-\frac{x_{\text{max}} - x_1 - x_{\text{peak}}}{\Lambda'}}$$

$$f_{\text{fluct}}(x_{\text{peak}}(E), \Lambda'(E), \alpha(E)) \Rightarrow f_{\text{fluct}}(E)$$

$$P_m(x_m) = N \int_0^{x_m - x_{\text{peak}} + \Lambda' \alpha} e^{\frac{-x_1}{\lambda_{p\text{-Air}}}} \left[ \frac{x_{\text{max}} - x_{\text{peak}} - x_1 + \Lambda' \alpha}{e} \right]^{\alpha} e^{-\frac{x_{\text{max}} - x_1 - x_{\text{peak}}}{\Lambda'}} dx_1;$$

# $X_{\max}$ and Energy Resolution– detector MC.

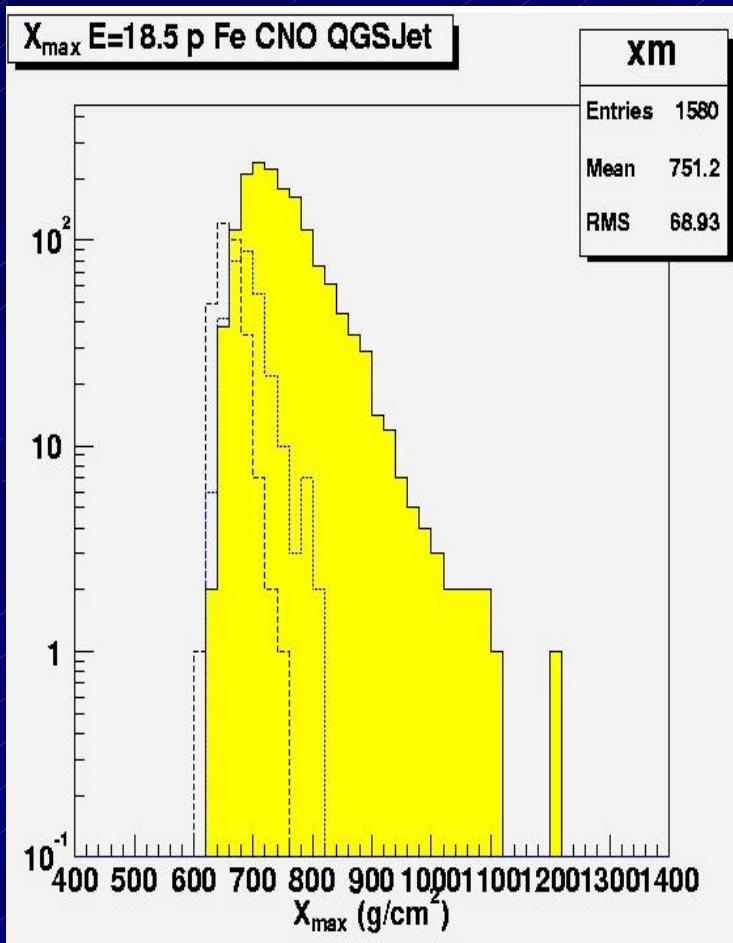

$$\Delta X_{\max} \approx 22 \text{ g/cm}^2$$

shift of  $\langle X_{\max} \rangle \approx 2 \text{ g/cm}^2$

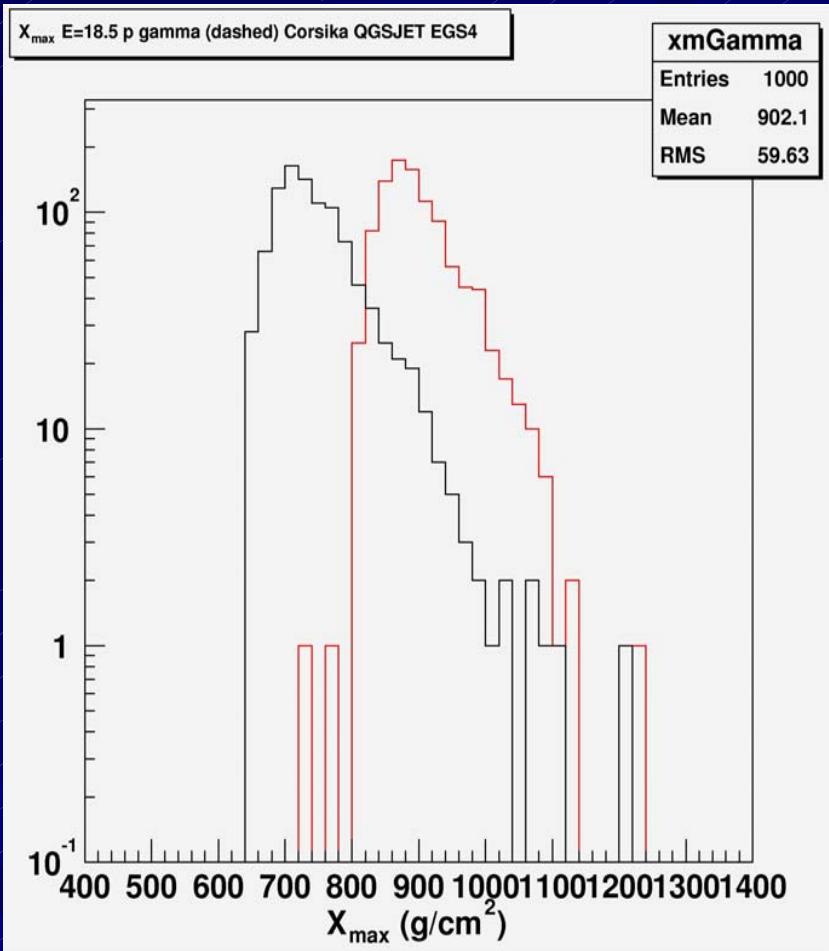

$$\Delta E = 12\%$$

# Composition influence – Fe & CNO.

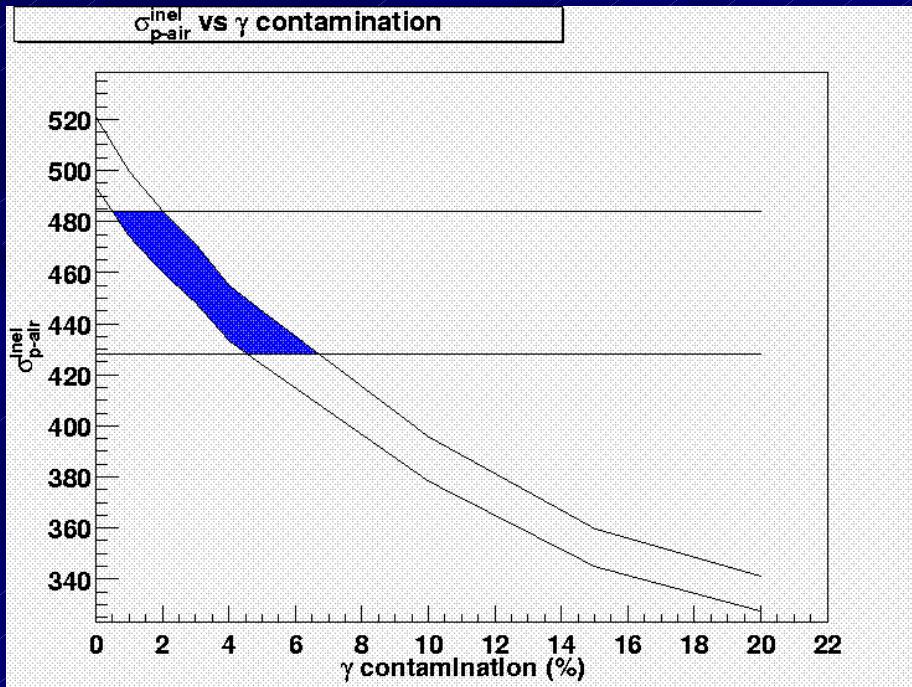

- 20% Fe is shown as dotted line.
- Heavier nuclei influence can be reduced by only using a part of the distribution deeper than 700 g/cm<sup>2</sup>.

# Composition influence – gamma.

- $\langle X_{\max} \rangle$  is  $\sim 130$  g/cm<sup>2</sup> deeper for gamma showers;
- Can not be simply cut off.

# Composition influence – gamma.

- For this cross-section study – a systematic error estimation due to gamma ray flux.

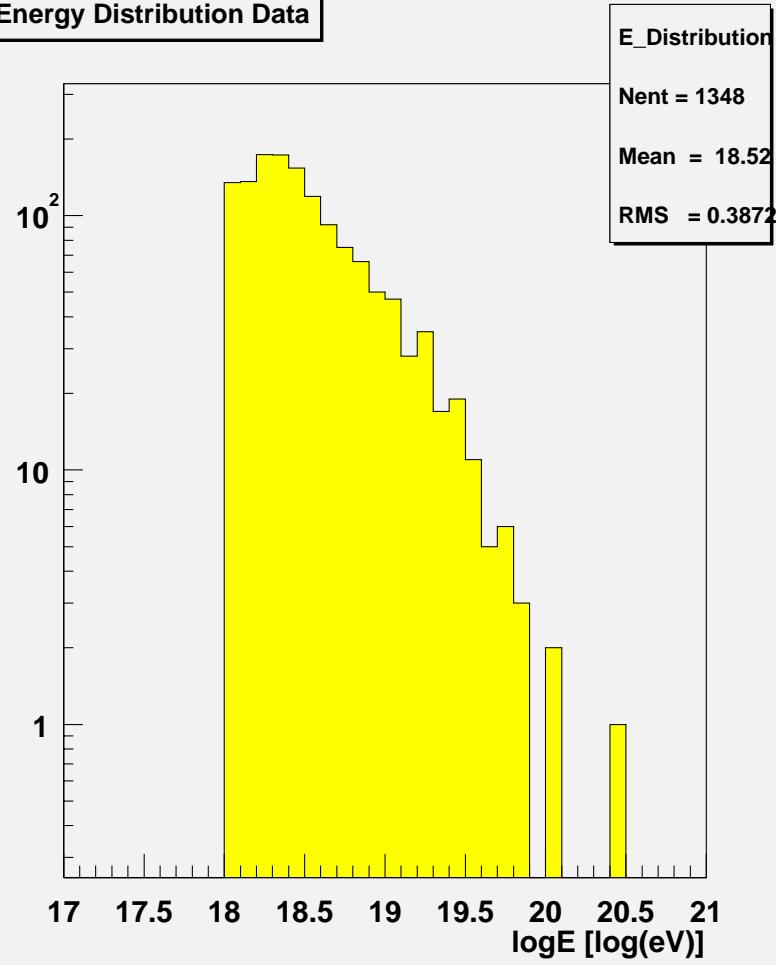

MC predicted p-air cross-section vs gamma flux.

# Possible $\lambda_{p-air}$ bias and systematic errors summary

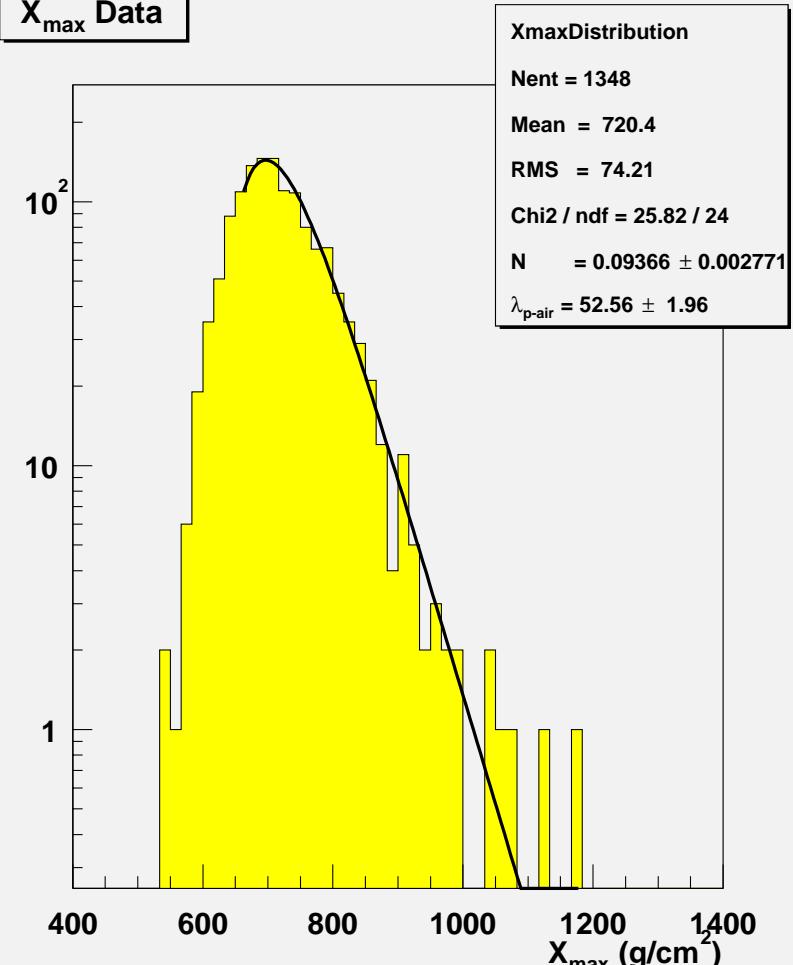

- Model dependence – negligible at shower development in the air energies.
- Detector trigger bias and Fe contamination – avoided by using 700 g/cm<sup>2</sup> or deeper portion of Xmax distribution.
- gamma contamination (assuming ~5% gamma flux) < 4 g/cm<sup>2</sup>.
- Reconstruction and quality cuts bias < 1.5 g/cm<sup>2</sup>
- Fitting bias < 1 g/cm<sup>2</sup>
- Atmosphere influence minimized by selecting only clear nights.

# Data

Energy Distribution Data

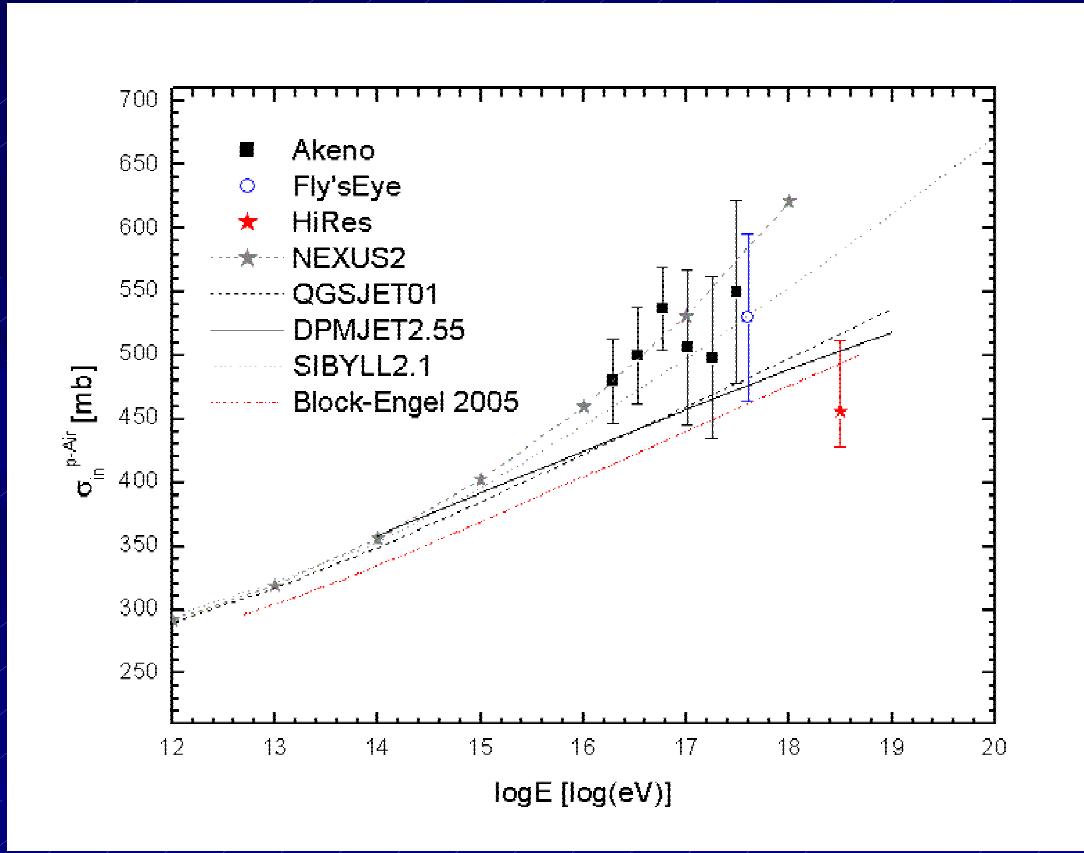

X<sub>max</sub> Data

- 1348 out of 3346 (thru March 2003) stereo events pass the quality cuts

# HiRes measurement.

$$\text{HiRes : } \sigma_{in}^{p\text{-Air}} = 456 \pm 17 (\text{stat}) + 39 (\text{sys}) - 11 (\text{sys}) \text{ mb}$$

# Conclusions

- $p$ -air inelastic cross-section measured by the HiRes stereo fluorescence detector at  $10^{18.5}$  eV is:

$$\sigma_{in}^{p-Air} = 456 \pm 17(stat) + 39(sys) - 11(sys) \text{ mb}$$

- Accelerator data extrapolation strongly favor the Froissart bound saturation! HiRes data is consistent with it.
- “A solid link between cosmic ray and accelerator measurements is established for the first time!” – M.Block.
- Gamma ray flux upper limit will improve systematic errors.
- CS energy trend – need more statistics to have some leverage.
